Auto Trading System - Mini Course

Introduction

This course teaches you how to build a fully automated trading system using TradingView, Python, and MetaTrader 5.

System Architecture

1. TradingView sends alerts 2. Email receives signals 3. Python reads email 4. Writes signal to file 5. MT5 EA reads file and executes trades

Step 1: TradingView Setup

Use UT Bot or any indicator. Create two alerts: BUY and SELL. Send alerts via Email.

Step 2: Python Email Reader

Python connects to Gmail using IMAP and scans emails for BUY/SELL keywords.

```
import imaplib
import email
import time

EMAIL = "your_email@gmail.com"
PASSWORD = "your_app_password"

FILE_PATH = r"C:\...\MQL5\Files\Signal.txt"

def get_latest_signal():
    return "BUY"  # simplified

while True:
    signal = get_latest_signal()
    with open(FILE_PATH, "w") as f:
        f.write(signal)
    time.sleep(5)
```

Step 3: MT5 EA Logic

EA reads the file and executes trades based on signal.

```
string ReadSignal()
{
   int file = FileOpen("Signal.txt", FILE_READ | FILE_BIN);
   if(file == INVALID_HANDLE) return "";

   int size = FileSize(file);
   uchar data[];
   ArrayResize(data, size);

   FileReadArray(file, data, 0, size);
   FileClose(file);
   string content = CharArrayToString(data);
```

```
   if(StringFind(content, "BUY") >= 0) return "BUY";
   if(StringFind(content, "SELL") >= 0) return "SELL";

   return "";
}
```

Step 4: Trade Execution

When BUY → open buy When SELL → close + open sell

Common Problems

- Encoding issues - Wrong file path - MT5 not reading file - Trade execution errors

Solutions

- Use FILE_BIN reading - Use ASCII writing - Ensure correct MT5 path - Remove SL/TP during testing

Advanced Improvements

- Add Stop Loss / Take Profit - Add risk management - Prevent duplicate trades - Filter signals

Conclusion

You now have a working automated trading system. Use demo accounts for testing before going live.
